Implement DFS and BFS algorithm

a) **AIM:** Write an application to implement DFS algorithm.

Code:

```
graph = {
    '5': ['3','7'],
    '3': ['2', '4'],
    '7': ['8'],
    '2': [],
    '4': ['8'],
    '8': []
}

visited = [] # List for visited nodes.
queue = []   #Initialize a queue

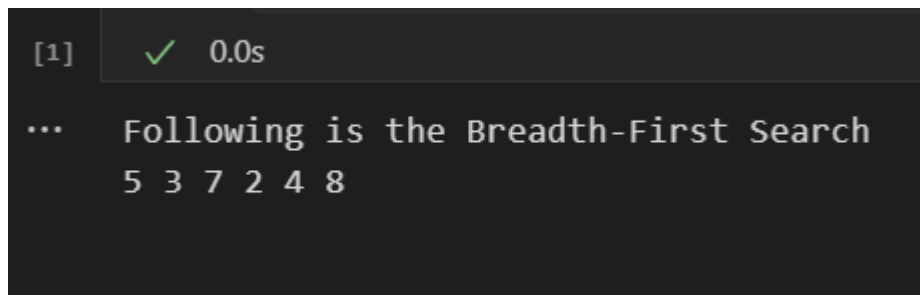

def bfs(visited, graph, node): #function for BFS
    visited.append(node)
    queue.append(node)

    while queue:          # Creating loop to visit each node
        m = queue.pop(0)
        print (m, end = " ")

        for neighbour in graph[m]:
            if neighbour not in visited:
                visited.append(neighbour)
                queue.append(neighbour)

# Driver Code
print("Following is the Breadth-First Search")
bfs(visited, graph, '5')# function calling
```

OUTPUT:

```
[1] ✓ 0.0s

... Following is the Breadth-First Search
5 3 7 2 4 8
```

b) Aim: Write an application to implement BFS algorithm.**Code:**

```
# Using a Python dictionary to act as an adjacency list
```

```
graph = {  
    '5': ['3','7'],  
    '3': ['2', '4'],  
    '7': ['8'],  
    '2': [],  
    '4': ['8'],  
    '8': []  
}
```

```
visited = set() # Set to keep track of visited nodes of graph.
```

```
def dfs(visited, graph, node): #function for dfs
```

```
    if node not in visited:
```

```
        print (node)
```

```
        visited.add(node)
```

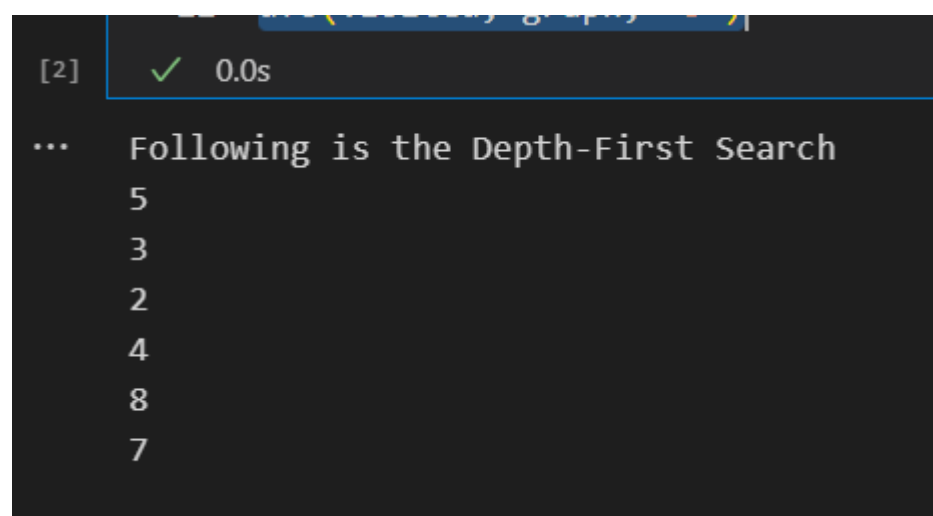

```
        for neighbour in graph[node]:
```

```
            dfs(visited, graph, neighbour)
```

```
# Driver Code
```

```
print("Following is the Depth-First Search")
```

```
dfs(visited, graph, '5')
```

OUTPUT:

```
[2] ✓ 0.0s  
... Following is the Depth-First Search  
    5  
    3  
    2  
    4  
    8  
    7
```
